Electrical connectors that join flexible circuits to a substrate are well known in the prior art. These connectors

typically have a housing and a plurality of contacts. The contacts are arranged for mating with corresponding contacts on the flexible circuit and the substrate. A compliant spring is disposed within the housing for deflecting the contacts in a coplanar manner to ensure a proper and consistent mating engagement between the contacts and the flexible circuit and the substrate. The prior art connectors suffer from a disadvantage in that there are limitations on the geometry of the flexible circuit and the substrate. These limitations typically take the form of bend radii that are too large or bend configurations that are too complicated. For example, most flexible circuits are bent in a generally U-

shaped configuration so as to be perpendicular to a substrate. Typically, the circuit is bent so as to form a loop, or both a loop and a perpendicular portion of a U-shaped circuit, with a bend radius of 1-2 millimeters. Bend radii of this size are dictated by the need for a low insertion force for the connector, which is necessary to ensure that the contact terminals are easily depressed against the flexible circuit and the substrate by a mating connector.
